### THIRD PARTY API'S

Transmitter is a module for connecting a third-party device with a wired output to an Ajax security system. The module has an alarm and tamper inputs (devices with NC/NO contact type are supported), and power output for connected devices.

## Features of Transmitter

- Makes a third-party wired device part of an Ajax security system.
- It can be installed indoors or outdoors (in the detector casing or a sealed box).
- Provides power supply to the connected device.
- Equipped with an accelerometer that will raise an alarm if someone tries to dismantle the Transmitter.
- Operates in temperatures from -25°C to +50°C and humidity up to 75% without condensation.

## Informative alarms, precise commands

After receiving information about alarms or events from a connected wired device, the module transmits it to an Ajax hub. You can select one of 8 types of events: intrusion, fire, medical help, panic button, gas alarm, malfunction, leakage, and custom. The type of event determines the alarm code sent to the security company monitoring station and the text of notification received by the user. This ensures an accurate response to the threat.

## Receive the alarms when the temperature exceeds the specified range

For this, a third-party thermostat is connected to the Transmitter. The temperature range is adjusted on the thermostat. To indicate the upper and lower extreme temperature, use the NO contacts on the alarm loops, and connect the NC contacts to the tamper contacts of the Transmitter.
